The.NET Framework provides Windows-based.NET client applications with a number of various useful classes, methods, and properties that can be accessed via the Framework Integration Interfaces. Most importantly, the Windows Forms, WPF, and UWP components provide us with the DataGrid, DataGridView, and ListView classes that you should use to display data within a Windows Forms application. However, you can achieve many useful things with these interfaces without having to resort to these DataGrid-based controls. For example, you can work with the SerialPort object to connect to various serial devices and perform various tests on them, which is useful in the development of console-based applications. Additionally, you can also display information regarding the system clock on the device or identify whether a device has received an interrupt. In this chapter, we will cover the basics of the Windows Forms, WPF, and UWP DataGrid, DataGridView, and ListView classes, and we will also explore some of their useful properties and methods. Accessing.NET Framework DataGrid, DataGridView, and ListView components There are three classes in the Windows Forms, WPF, and UWP DataGrid, DataGridView, and ListView components package: The System.Windows.Forms.DataGrid class enables you to display multiple, single- or multicolumned, or even mixed grid data sets (both locally and remotely). It provides various methods to determine the number of columns and rows, manipulate the virtual columns and rows, change the column and row headings, and more. The System.Windows.Forms.DataGridView class is similar to the System.Windows.Forms.DataGrid class, and it is the core class of the WPF and UWP components. However, it has the ability to handle a large number of columns and rows, and it enables you to control its virtual columns and rows through various properties and methods. Finally, the System.Windows.Forms.ListView class provides you with the ability to add, remove, and arrange columns and rows to create a customizable list control. SerialPort Properties To work with serial ports, you should be familiar with the following properties and methods: You can get a reference to a SerialPort object by using the static SerialPort.GetPortNames() method. This method returns an array of strings that identifies the serial ports on the machine. Each string includes the manufacturer of the device and a device ID that

I am having a problem when trying to reorder raster images in ArcMap. I have a very large number of raster images, each named "RasterB" through "RasterZ". I have a folder with over 20 images of different size. I want to reorder them in the descending order of the name. I used to do this by right-clicking on the raster, choosing "Reorder" and then I would drag the raster up or down. I have tried it with ArcGIS 10.0.1, 10.1, 10.2 and 10.3. When I do it, it does not sort them in descending order but instead creates one image with the name of the first one, one with the name of the second one, etc. So, for example, if I have 3 raster images, they are Raster A, B, and C. They are in ascending order of size, A being the smallest, B being bigger than A, and C being the biggest. I want to reorder them in the order B, C, A. But, when I do this, ArcGIS creates one image with the name of the first raster, then one with the name of the second, then one with the name of the third. So, my results are: Raster A, B, C Raster A, B, C Raster A, B, C How can I do this? A: I am not sure
